Causality

Dominik Janzing & Bernhard Schölkopf Max Planck Institute for Intelligent Systems Tübingen, Germany

http://ei.is.tuebingen.mpg.de

A Modeling Taxonomy

model	predict in IID setting	predict under changing distributions / interventions	answer counter- factual questions	obtain physical insight	automatically learn from data
mechanistic model	Y	Y	Y	Y	?
structural causal model	Y	Y	Y	N	Y??
causal graphical model	Y	Y	N	N	Y?
statistical model	Y	N	N	N	Y

"Correlation does not tell us anything about causality"

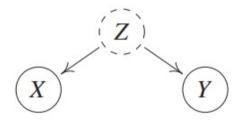

- Better to talk of dependence than correlation
- Most statisticians would agree that causality does tell us something about dependence
- But dependence does tell us something about causality too:

Principle 1.1 (Reichenbach's common cause principle) If two random variables X and Y are statistically dependent $(X \not\perp Y)$, then there exists a third variable Z that causally influences both. (As a special case, Z may coincide with either X or Y.) Furthermore, this variable Z screens X and Y from each other in the sense that given Z, they become independent, $X \perp\!\!\!\perp Y \mid Z$.

What is cause and what is effect?

$$p(a,t) = p(a|t) \ p(t)$$
 $T \to A$
= $p(t|a) \ p(a)$ $A \to T$

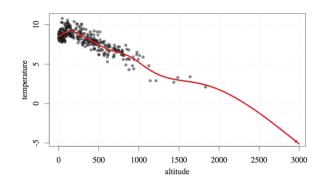

Autonomous/invariant mechanisms

- intervention on a: raise the city, find that t changes
- hypothetical intervention on a: still expect that t changes, since we can think of a physical mechanism p(t|a) that is independent of p(a)
- we expect that p(t|a) is invariant across, say, different countries in a similar climate zone

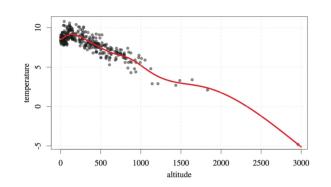

Independence of cause & mechanism

- the conditional density p(t|a) (viewed as a function of t and a) provides no information about the marginal density function p(a)
- this also applies if we only have a single density

Independence of noise terms

• view the distribution as entailed by a structural causal model (SCM)

$$A := N_A,$$

$$T := f_T(A, N_T),$$

where $N_T \perp \!\!\! \perp N_A$

• this allows identification of the causal graph under suitable restrictions on the functional form of f_T

Pearl's do-notation

• Motivation: goal of causality is to infer the effect of interventions

 \bullet distribution of Y given that X is set to x:

$$p(Y|do X = x)$$
 or $p(Y|do x)$

- don't confuse it with P(Y|x)
- \bullet can be computed from p and G

Difference between seeing and doing

p(y|x)

probability that someone gets 100 years old given that we know that he/she drinks 10 cups of coffee per day

p(y|dox)

probability that some randomly chosen person gets 100 years old after he/she has been forced to drink 10 cups of coffee per day

The Principle of Independent Mechanisms

Principle 2.1 (**Independent mechanisms**) The causal generative process of a system's variables is composed of autonomous modules that do not inform or influence each other.

In the probabilistic case, this means that the conditional distribution of each variable given its causes (i.e., its mechanism) does not inform or influence the other conditional distributions. In case we have only two variables, this reduces to an independence between the cause distribution and the mechanism producing the effect distribution.

Example 3.2 (Cause-effect interventions) Suppose that the distribution $P_{C,E}$ is entailed by an SCM \mathfrak{C}

$$C := N_C$$

$$E := 4 \cdot C + N_E,$$
(3.3)

with $N_C, N_E \stackrel{\text{iid}}{\sim} \mathcal{N}(0, 1)$, and graph $C \to E$. Then,

Example: Smoking and Teeth Color

Computing $p(X_k|do x_i)$

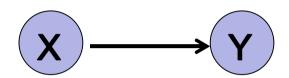

summation over x_i yields

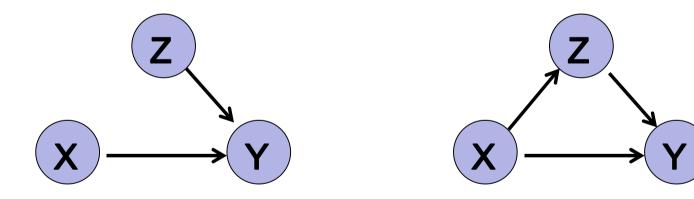

$$p(X_1, \ldots, X_{i-1}, X_{i+1}, \ldots, X_n | do x_i) = \prod_{j \neq i} p(X_j | PA_j(x_i)).$$

- distribution of X_j with $j \neq i$ is given by dropping $p(X_i|PA_i)$ and substituting x_i into PA_j to get $PA_j(x_i)$.
- obtain $p(X_k|do x_i)$ by marginalization

Examples for p(.|do x) = p(.|x)

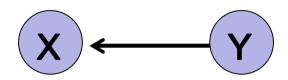

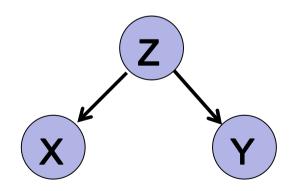

Examples for $p(.|do x) \neq p(.|x)$

• $p(Y|do x) = P(Y) \neq P(Y|x)$

• $p(Y|do x) = P(Y) \neq P(Y|x)$

Inferring the DAG

• Key postulate: Causal Markov condition

• Essential mathematical concept: d-separation (describes the conditional independences required by a causal DAG)

Causal faithfulness

Spirtes, Glymour, Scheines

p is called faithful relative to G if only those independences hold true that are implied by the Markov condition, i.e.,

$$(X \perp\!\!\!\perp Y \mid Z)_G \quad \Leftarrow \quad (X \perp\!\!\!\perp Y \mid Z)_p$$

Recall: Markov condition reads

$$(X \perp\!\!\!\perp Y \mid Z)_G \quad \Rightarrow \quad (X \perp\!\!\!\perp Y \mid Z)_p$$

Examples of unfaithful distributions (1)

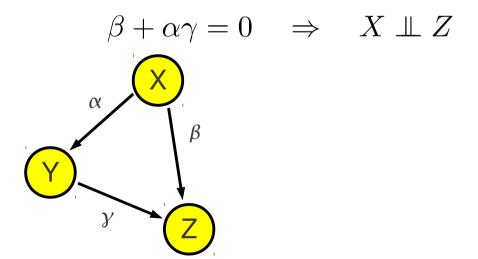

Cancellation of direct and indirect influence in linear models

$$X = U_X$$

$$Y = \alpha X + U_Y$$

$$Z = \beta X + \gamma Y + U_Z$$

with independent noise terms U_X, U_Y, U_Z

Markov equivalence class

Theorem (Verma and Pearl, 1990): two DAGs are Markov equivalent iff they have the same skeleton and the same v-structures.

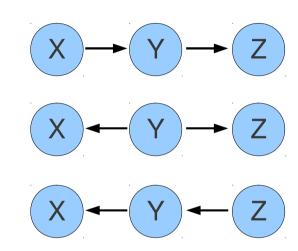

skeleton: corresponding undirected graph

v-structure: substructure $X \to Y \leftarrow Z$ with no edge between

X and Z

Markov equivalent DAGs

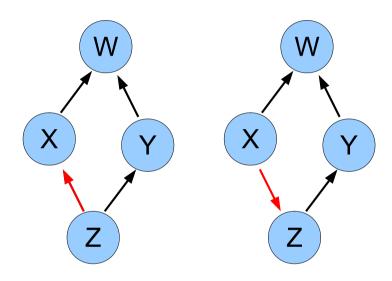

same skeleton, no v-structure

$$X \perp\!\!\!\perp Z \mid Y$$

Markov equivalent DAGs

same skeleton, same v-structure at W

Efficient construction of skeleton

PC algorithm by Spirtes & Glymour (1991)

iteration over size of Sepset

- 1. remove all edges X Y with $X \perp \!\!\!\perp Y$
- 2. remove all edges X-Y for which there is a neighbor $Z \neq Y$ of X with $X \perp\!\!\!\perp Y \mid Z$
- 3. remove all edges X Y for which there are two neighbors $Z_1, Z_2 \neq Y$ of X with $X \perp \!\!\! \perp Y \mid Z_1, Z_2$

4. ...

Advantages

- many edges can be removed already for small sets
- testing all sets S_{XY} containing the adjacencies of X is sufficient
- depending on sparseness, algorithm only requires independence tests with small conditioning tests
- polynomial for graphs of bounded degree

Find v-structures

- given X Y Z with X and Y non-adjacent
- given S_{XY} with $X \perp \!\!\! \perp Y \mid S_{XY}$

a priori, there are 4 possible orientations:

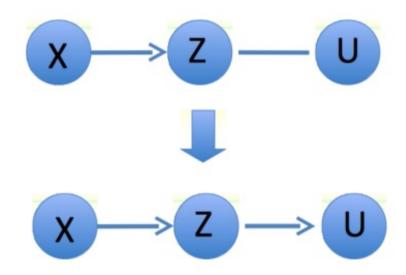

$$X \to Z \to Y$$

 $X \leftarrow Z \to Y$
 $X \leftarrow Z \leftarrow Y$
 $Z \in S_{XY}$
 $Z \notin S_{XY}$

Orientation rule: create v-structure if $Z \notin S_{XY}$

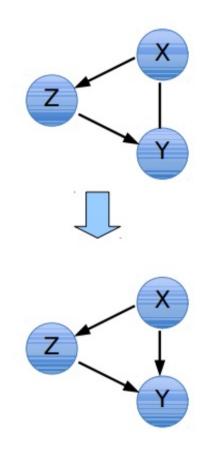

Direct further edges (Rule 1)

(otherwise we get a new v-structure)

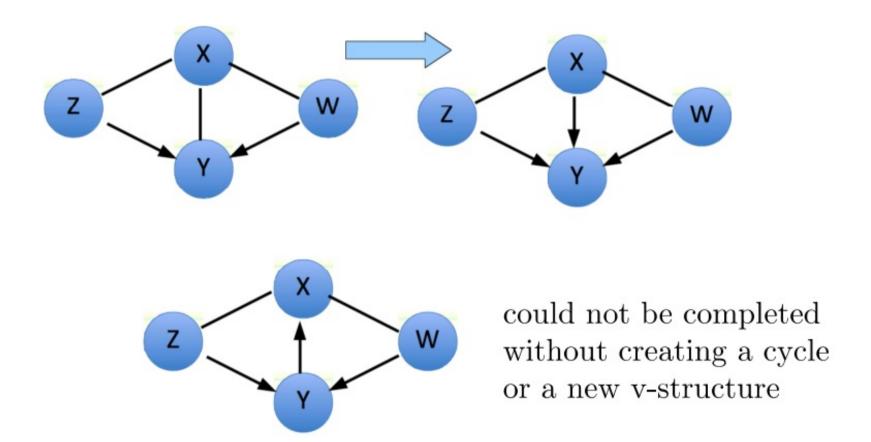

Direct further edges (Rule 2)

(otherwise one gets a cycle)

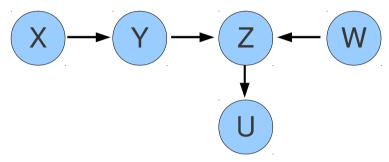

Direct further edges (Rule 3)

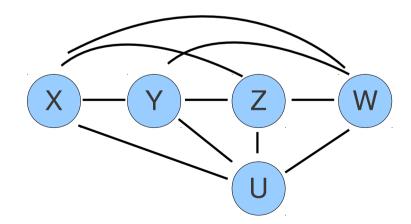

Examples

(taken from Spirtes et al, 2010) true DAG

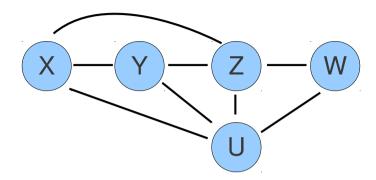

start with fully connected undirected graph

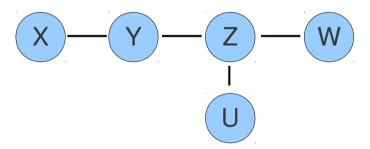

remove all edges X - Y with $X \perp \!\!\! \perp Y \mid \emptyset$

$$X \perp \!\!\! \perp W \quad Y \perp \!\!\! \perp W$$

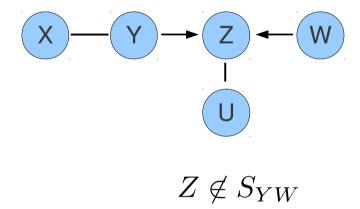

remove all edges having Sepset of size 1

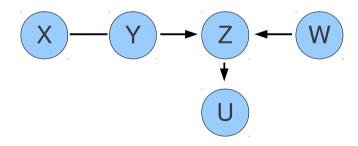

$$X \perp\!\!\!\perp Z \mid Y - X \perp\!\!\!\perp U \mid Y - Y \perp\!\!\!\perp U \mid Z - W \perp\!\!\!\perp U \mid Z$$

find v-structure

orient further edges (no further v-structure)

edge X - Y remains undirected
